The abstract TrainService class was used to create an interface requiring each train type to explain what their service does.
The abstract Lrt2Train class was used to store common data and functionality between all trains. LocalTrain and ExpressTrain were created as separate classes to allow them to explain what their service does, whilst also allowing them to customise how their status is shown.
The passenger count is private so it can't be accessed outside of the class. The constructor validates the capacity and initial passenger count whilst the board method will stop passengers boarding if the train is full.
The menu loop allows the user to perform various actions until they choose to exit. Async and await was used to mimic saving a train record, this would pause for a moment and then display the confirmation message.
PassengerMessaging mixin was also used to allow the station kiosk to make announcements without being a train. Overall these helped to keep my program well organised and allowed me to use abstraction, inheritance, polymorphism, user input and async code.
